

# MONTHLY COMMODITY TRADING REPORT

## Metric & Chart Dictionary

A plain-English guide for non-technical stakeholders

### WHAT THIS DOCUMENT EXPLAINS

- What each metric means
- How each metric is calculated
- How to read each chart
- How Year and Month filters affect results
- What the dashboard should and should not be used for

### CORE REPORT AREAS

Trading activity | Settlement status | Cash flow  
Trade counts | Position | Commodity analysis

Designed for monthly reporting, governance and stakeholder interpretation

## 1

## REPORT AT A GLANCE

The monthly report combines activity, cash flow, settlement and position information.

### Purpose of this dictionary

Use this document to understand what each metric represents, how it is calculated, how filters affect it and which business questions each chart can support. It is written for readers who do not need to understand DAX or the underlying data model.

| Term | Meaning                     | Calculation / note                                                    |
|------|-----------------------------|-----------------------------------------------------------------------|
| 1    | Headline KPI cards          | Six high-level indicators for the selected reporting month.           |
| 2    | Monthly performance summary | Current month values and percentage change versus the previous month. |
| 3    | Daily trade notional        | Daily Buy and Sell contract value within the selected month.          |
| 4    | Monthly trade statistics    | Trade-count ratios, settlement ratios and trade-size statistics.      |
| 5    | Performance by period       | Monthly, quarter-to-date and year-to-date context.                    |
| 6    | Cumulative net cash flow    | Running cash movement based on settlement dates.                      |
| 7    | Weekly performance          | Weekly Buy/Sell notional plus distinct trade count.                   |
| 8    | Commodity analysis          | Notional, Buy/Sell mix and contract-versus-market price by commodity. |

### How to use each metric page

- Start with What it means for the business definition.
- Review How it is calculated for the calculation logic.
- Use How to read it for interpretation guidance.
- Check Limitations before making a decision.

### Key report conventions

- Currency is shown in US\$.
- K, M and B mean thousand, million and billion.
- Trade counts use distinct Trade ID.
- The selected reporting month controls monthly visuals.

## 2

## HOW THE REPORT CALCULATES AND FILTERS DATA

These rules apply across the custom SVG visuals and metric cards.

### Data sources

- FactTrading: merged trade, settlement and market-price data at trade/cash-record level.
- Position: periodic purchased volume, sold volume and reported position by commodity.
- Trade Date drives trading-activity charts.
- Settlement Date drives cash-flow charts.
- Position Date drives month-end and latest-position metrics.

### Display conventions

- Currency is displayed as US\$.
- K means thousand, M means million and B means billion.
- Dates use en-GB labels, for example 30 Jun 2026.
- Trade counts use distinct Trade ID, not the number of table rows.
- Blank prior periods display no comparison rather than an artificial percentage.

### Report Month behaviour

The Year/Month hierarchy on MonthStart identifies the reporting month. With one month selected, that month is used. With multiple months selected, the latest selected month is used. With no selection, the latest available month is used.

### Comparison visuals

Buy-versus-Sell visuals deliberately show both sides even when a Type filter exists. Settled-versus-Pending visuals deliberately show both statuses. Other active filters, such as Commodity, are reapplied to the calculation.

**FOUR SIMPLE EXAMPLES**

Trade notional:  $100 \text{ units} \times \text{US\$}9,000 = \text{US\$}900,000$

Net cash flow:  $\text{US\$}1.20\text{M inflows} - \text{US\$}0.90\text{M outflows} = \text{US\$}0.30\text{M}$

Monthly change:  $(\text{US\$}12.5\text{M} - \text{US\$}11.5\text{M}) / \text{US\$}11.5\text{M} = 8.7\%$

Net position:  $700 \text{ purchased} - 550 \text{ sold} = +150 \text{ long}$

**Filter context note**

The responsive measures clear the inherited Year/Month hierarchy inside the SVG calculation, then reapply the selected month and relevant business filters. This prevents a selected month from producing a blank chart.

## 3

## HEADLINE METRICS - TRADING ACTIVITY

The first two KPI cards describe the scale of trading activity.

### Total Trade Notional [Total Trade Notional]

**Business question:** How much contractual value was traded?

**Plain-English definition:** The gross contract value of every included Buy and Sell trade.

**Calculation:** For each trade, calculate Volume x Contract Price. Sum the results across all included trades.

**How to interpret:** A higher value means greater trading activity or contractual exposure. It does not by itself indicate good or bad performance.

**Date and filter basis:** Uses the selected report month and current business filters. Trade-level activity is aligned to Trade Date / MonthStart.

**Important watch-outs:** Notional is not accounting revenue, profit, cash movement or mark-to-market value. Buy and Sell trades are both added as positive activity.

### Total Traded Volume [Total Traded Volume]

**Business question:** How much physical or contractual quantity was traded?

**Plain-English definition:** The total Volume recorded for all included trades.

**Calculation:** Sum the Volume field across included trade records.

**How to interpret:** Useful for understanding activity level independently of price. A high notional may come from high volume, high price, or both.

**Date and filter basis:** Uses the selected report month and current filters such as Commodity and Type.

**Important watch-outs:** Confirm that volume units are consistent before combining commodities. A total across different unit conventions may not be economically meaningful.

#### RELATIONSHIP BETWEEN VOLUME, PRICE AND NOTIONAL

Notional increases when Volume increases.

Notional also increases when Contract Price increases.

Two months can have similar volume but very different notional because prices changed.

## 4

## HEADLINE METRICS - CASH AND SETTLEMENT

These indicators use settlement records rather than only trade execution records.

**Net Cash Flow** *[Net Cash Flow]*

**Business question:** Did the selected period create a net cash receipt or a net cash payment?

**Plain-English definition:** Signed cash movement after treating Inflow records as positive and Outflow records as negative.

**Calculation:** Sum Amount for Inflow records, then subtract Amount for Outflow records.

**How to interpret:** A positive result means net cash received. A negative result means net cash paid.

**Date and filter basis:** Cash-flow timing is based on Settlement Date. The metric follows active Commodity, Status, Cash Type and Trade Type filters in the current responsive visuals.

**Important watch-outs:** Net cash flow is not profit. A profitable trade can create a cash outflow, and a cash inflow can relate to an earlier trade. Pending records are included or excluded according to the Status filter.

**Pending Amount** *[Pending Amount]*

**Business question:** How much settlement value is still awaiting completion?

**Plain-English definition:** The gross Amount attached to settlement records whose Status is Pending.

**Calculation:** Sum Amount where Status = Pending.

**How to interpret:** A lower value often indicates less unresolved settlement exposure. A rising value may require operational follow-up.

**Date and filter basis:** Uses settlement records associated with the selected report month and other active filters.

**Important watch-outs:** This is a gross amount, not a signed cash forecast. It does not automatically mean overdue; a pending item may still be within its expected settlement window.

**Useful follow-up**

For operational action, split Pending Amount by expected inflow versus expected outflow, commodity, settlement date and ageing bucket.

## 5

## HEADLINE METRICS - TRADE COUNT AND POSITION

These metrics describe transaction frequency and open directional exposure.

### Total Trades *Distinct count of FactTrading[Trade ID]*

**Business question:** How many unique trades are included?

**Plain-English definition:** The number of different Trade IDs after applying the selected filters.

**Calculation:** Count each Trade ID once, even when the merged table contains more than one related row.

**How to interpret:** Useful for distinguishing a few large trades from many small trades.

**Date and filter basis:** Uses the selected report month and active filters.

**Important watch-outs:** Do not compare this directly with raw row count. A merged dataset can contain repeated Trade IDs because of cash or price records.

### Month-End Position *Latest monthly reported position*

**Business question:** What is the latest net volume position in the selected month?

**Plain-English definition:** The sum of Reported Position on the latest available Position date within the selected month.

**Calculation:** For each commodity, Reported Position represents Purchased Volume - Sold Volume. The KPI sums the latest included commodity positions.

**How to interpret:** Positive means net long volume; negative means net short volume. The magnitude shows directional exposure in volume units.

**Date and filter basis:** Uses the Position table and the latest available Position Date inside the selected month. Commodity filtering requires the Position table to receive the same commodity context.

**Important watch-outs:** This is volume exposure, not US\$ market value. The latest available date may be earlier than the calendar month-end if no later position record exists.

| Term                     | Meaning                            | Calculation / note                                              |
|--------------------------|------------------------------------|-----------------------------------------------------------------|
| Buy Notional             | Contract value of Buy trades       | Sum of Volume x Contract Price where Type = Buy.                |
| Sell Notional            | Contract value of Sell trades      | Sum of Volume x Contract Price where Type = Sell.               |
| Buy / Sell Trades        | Unique trade counts by side        | Distinct Trade ID where Type is Buy or Sell.                    |
| Settled / Pending Trades | Unique counts by settlement status | Distinct Trade ID where Status is Settled or Pending.           |
| Average Trade Value      | Typical notional per unique trade  | Total Trade Notional divided by Total Trades.                   |
| Largest Trade Value      | Largest single-trade notional      | Maximum total notional calculated separately for each Trade ID. |

## 6

## SUPPORTING CALCULATIONS

These values appear inside summary tables, ratios and comparison charts.

| Term                          | Meaning                                          | Calculation / note                                                                            |
|-------------------------------|--------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>Buy share</b>              | Share of unique trades that are Buy              | Buy Trades / (Buy Trades + Sell Trades).                                                      |
| <b>Sell share</b>             | Share of unique trades that are Sell             | Sell Trades / (Buy Trades + Sell Trades).                                                     |
| <b>Settled share</b>          | Share of classified settlements that are settled | Settled Trades / (Settled Trades + Pending Trades).                                           |
| <b>Pending share</b>          | Share of classified settlements still pending    | Pending Trades / (Settled Trades + Pending Trades).                                           |
| <b>Monthly change %</b>       | Movement versus the previous month               | (Current Month - Previous Month) / Previous Month x 100.                                      |
| <b>Average Contract Price</b> | Average agreed trade price                       | Arithmetic average of Contract Price for included trade rows.                                 |
| <b>Average Market Price</b>   | Average reference market price                   | Arithmetic average of Market Price for included rows.                                         |
| <b>Price difference</b>       | Contract price relative to market                | Average Contract Price - Average Market Price.                                                |
| <b>Quarter to Date</b>        | Activity from quarter start to report month-end  | Sum of Total Trade Notional from the first day of the quarter through the selected month-end. |
| <b>Year to Date</b>           | Activity from 1 January to report month-end      | Sum of Total Trade Notional from 1 January through the selected month-end.                    |

### Price interpretation depends on trade side

For a Buy, a contract price below market is generally favourable. For a Sell, a contract price above market is generally favourable. The price chart alone is not a profit-and-loss calculation.

### Period comparator governance

Use a consistent published definition: month versus previous month, previous month versus the month before, quarter-to-date versus the preceding comparable quarter, and year-to-date versus the same period in the prior year.

## 7

## SUMMARY AND PERIOD CHARTS

These visuals provide the fastest management-level reading of the month.

### Monthly Performance Summary

**What it shows:** A compact table of Trade Notional, Traded Volume, Buy Notional, Sell Notional, Net Cash Flow and Pending Settlement for the selected month.

**How it is calculated:** Each current-month value is calculated using the relevant base metric. Percentage change equals (current month - previous month) / previous month.

**How to read it:** Read the middle column for the selected-month value and the right column for direction and magnitude of change. Pending Settlement uses a lower-is-better interpretation; most activity metrics use higher-is-better colouring.

**Filter behaviour:** The selected report month is reapplied after clearing the MonthStart hierarchy. Buy and Sell rows deliberately display both sides. Other captured business filters remain active.

**Business use:** Use it to identify which part of the month changed: volume, price-driven notional, cash movement, or unresolved settlement.

**Cautions:** A favourable colour is a visual convention, not a full risk assessment. No comparison is shown when the prior-period value is blank or zero.

### Performance by Period

**What it shows:** Trading notional viewed across This Month, Previous Month, Quarter to Date and Year to Date.

**How it is calculated:** This Month uses selected-month notional; Previous Month uses the prior calendar month; Quarter to Date sums from quarter start; Year to Date sums from 1 January. The change column compares each row with its defined preceding comparable period.

**How to read it:** Use the monthly rows for near-term movement and QTD/YTD rows for broader context. A strong month may still sit inside a weaker quarter or year.

**Filter behaviour:** Uses the selected report month as the period end and follows the relevant dashboard filters.

**Business use:** Helps management avoid overreacting to one month and distinguish short-term volatility from sustained activity.

**Cautions:** QTD and YTD comparisons must use a documented comparator. Do not compare a partial period with a full period without clear labelling.

## 8

## DAILY TRADE NOTIONAL

A day-by-day view of Buy and Sell contract value during the selected month.

### Daily Trade Notional

**What it shows:** Grouped bars show Buy Notional and Sell Notional for each calendar day in the report month.

**How it is calculated:** For each day: Buy bar = sum of Volume x Contract Price for Buy trades on that Trade Date. Sell bar uses the same calculation for Sell trades. Days without trades are zero.

**How to read it:** Compare bar height to identify active trading days, clusters of activity and differences between the Buy and Sell sides. The axis is US\$ notional.

**Filter behaviour:** The chart clears the Year/Month hierarchy, applies the selected month as a daily date range, and reapplies Commodity, Status and Cash Type selections. The Type filter is deliberately ignored so both Buy and Sell remain visible.

**Business use:** Useful for identifying execution spikes, month-end concentration and days that may require explanation or review.

**Cautions:** A high bar is high contractual activity, not necessarily high cash flow or profit. Daily bars may be driven by one large trade rather than many trades.

#### DAILY CALCULATION EXAMPLE

2 Jun Buy trades: US\$400K + US\$250K = US\$650K Buy Notional

2 Jun Sell trades: US\$300K = US\$300K Sell Notional

The chart displays two separate bars for 2 Jun.

#### Date labels

The chart calculates all days in the month but labels selected ticks such as 1 Jun, 6 Jun, 11 Jun, 16 Jun, 21 Jun, 26 Jun and the final day to keep the axis readable.

## 9

## MONTHLY TRADE STATISTICS

Count-based ratios and trade-size statistics for the selected month.

### Buy : Sell Ratio

**What it shows:** The distribution of unique trades between Buy and Sell.

**How it is calculated:** Buy share = Buy Trades / (Buy Trades + Sell Trades). Sell share uses the same denominator. The donut and labels are based on trade count, not US\$ value.

**How to read it:** A 54:46 ratio means 54% of classified trades are Buy and 46% are Sell.

**Filter behaviour:** The ratio intentionally ignores a Type filter to keep both sides visible, while reapplying Commodity, Cash Type and Status filters.

**Business use:** Useful for understanding transaction direction and operational workload by side.

**Cautions:** A count-balanced month can still be heavily unbalanced by notional or volume when trade sizes differ.

### Settled : Pending Ratio

**What it shows:** The distribution of unique classified trades between Settled and Pending.

**How it is calculated:** Settled share = Settled Trades / (Settled Trades + Pending Trades). Pending share uses the same denominator.

**How to read it:** A rising Pending share indicates a larger proportion of trades awaiting settlement and may warrant follow-up.

**Filter behaviour:** The ratio intentionally ignores a Status filter to display both categories. Commodity, Cash Type and Trade Type filters remain active.

**Business use:** Useful for settlement monitoring and prioritising operational attention.

**Cautions:** Pending is not the same as overdue. The chart requires status values to match the model labels Settled and Pending.

### Statistics shown under the donuts

Total Trades, Buy Trades, Sell Trades, Total Settled, Total Pending, Average Trade Value and Largest Trade Value are calculated from distinct Trade IDs and trade-level notional.

## 10

## CUMULATIVE NET CASH FLOW

A running view of settlement cash movement through the selected month.

### Cumulative Net Cash Flow

**What it shows:** The line shows the month-to-date total of signed cash movement on each settlement date.

**How it is calculated:** Daily Net Cash Flow = Inflow Amount - Outflow Amount for that day. Cumulative value on a date = sum of Daily Net Cash Flow from the first day of the month through that date.

**How to read it:** An upward segment means the day added positive net cash. A downward segment means the day added negative net cash. The final callout is the selected month-end cumulative result.

**Filter behaviour:** The visual clears the Year/Month hierarchy, uses Settlement Date for the daily range, and reapplies selected Commodity, Status, Cash Type and Trade Type filters.

**Business use:** Useful for liquidity monitoring, identifying cash concentration dates and explaining the month-end net cash position.

**Cautions:** The cumulative line is not cumulative profit. It can include Pending or Settled records depending on the active Status filter. A flat line means no net cash movement, not necessarily no trade activity.

#### RUNNING-TOTAL EXAMPLE

Day 1 net cash flow: +US\$500K -> cumulative US\$500K

Day 2 net cash flow: -US\$200K -> cumulative US\$300K

Day 3 net cash flow: +US\$700K -> cumulative US\$1.00M

#### Negative values are valid

The scale includes zero and can extend below zero. A negative cumulative value means net cash paid exceeds net cash received within the selected month-to-date window.

## 11

## WEEKLY PERFORMANCE

A simplified weekly view that combines notional activity and trade frequency.

### Weekly Performance

**What it shows:** Three lines show Buy Notional, Sell Notional and distinct Trades across fixed week buckets within the selected month.

**How it is calculated:** W1 = days 1-7, W2 = 8-14, W3 = 15-21, W4 = 22-28 and W5 = 29 to month-end. Buy/Sell values are weekly sums of Volume x Contract Price. Trades is the weekly distinct Trade ID count.

**How to read it:** Use the Buy and Sell lines to compare contract-value activity. Use the Trades line to see whether a notional increase came from more trades or larger trades.

**Filter behaviour:** Buy and Sell lines deliberately ignore the Type filter so both are shown. The Trades line respects the selected Type filter. Commodity, Status and Cash Type selections are reapplied.

**Business use:** Useful for identifying intra-month peaks, workload concentration and the relationship between frequency and trade size.

**Cautions:** The notional lines and trade-count line use different scales. Their vertical heights cannot be compared as if they shared the same unit. Week buckets are calendar-day buckets, not ISO weeks.

### WEEKLY INTERPRETATION EXAMPLE

W3 notional rises while Trades stay flat -> average trade size increased.

W4 Trades rise while notional stays flat -> more, smaller trades occurred.

Buy and Sell lines moving together -> overall activity increased on both sides.

## 12

## COMMODITY ANALYSIS CHARTS

These visuals explain where activity and price differences are concentrated.

### Trade Notional by Commodity

**What it shows:** Ranks commodities by total contract value and may also show each commodity share of selected notional.

**How it is calculated:** For each commodity, sum Volume x Contract Price across included trades. Percentage share = commodity notional / total included notional.

**How to read it:** Longer bars indicate more contractual activity or exposure in US\$.

**Filter behaviour:** Responds to the selected month and applicable filters. When an Others group is used, it combines commodities outside the displayed top set.

**Business use:** Useful for concentration analysis, management focus and explaining which commodities drove the monthly total.

**Cautions:** High notional is not the same as high risk or profit. Expensive commodities can rank highly even with modest volume.

### Buy vs Sell Notional by Commodity

**What it shows:** Compares Buy and Sell contract value for each commodity.

**How it is calculated:** For each commodity, calculate Buy Notional and Sell Notional separately using Volume x Contract Price.

**How to read it:** A large gap shows directional imbalance in contractual activity. Review it alongside net position and price levels.

**Filter behaviour:** The Type filter should be ignored inside this comparison so both Buy and Sell remain visible; other report filters remain active.

**Business use:** Useful for identifying commodities with one-sided trading activity and for explaining changes in net position.

**Cautions:** Notional imbalance does not equal position imbalance when trades occur at different times, prices or settlement states.

### Contract vs Market Price (Average)

**What it shows:** Compares the average agreed Contract Price with the average reference Market Price for each commodity.

**How it is calculated:** Calculate the arithmetic average of Contract Price and the arithmetic average of Market Price for included rows.

**How to read it:** For Buy trades, contract below market is generally favourable; for Sell trades, contract above market is generally favourable. Review the numerical gap and trade side together.

**Filter behaviour:** Responds to selected month, commodity and other business filters.

**Business use:** Useful for identifying pricing differences that require commercial explanation or deeper trade-level review.

**Cautions:** An arithmetic average is not volume-weighted unless the model explicitly uses weighting. The comparison is not realised or unrealised P&L and may be affected if market prices are repeated across merged rows.

## 13

EXECUTIVE OVERVIEW CHARTS AND INTERPRETATION  
GUARDRAILS

Shared measures may also appear on the broader dashboard overview page.

| Term                                    | Meaning                               | Calculation / note                                                                                                                                 |
|-----------------------------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Monthly Trade Notional</b>           | Trend of total notional by month      | Each point is monthly sum of Volume x Contract Price. Use it for seasonality and trend, not profitability.                                         |
| <b>Buy vs Sell Volume</b>               | Volume comparison by commodity        | Grouped bars sum Volume separately for Buy and Sell. Useful when price differences would distort notional.                                         |
| <b>Volume Share by Commodity</b>        | Composition of traded volume          | Each slice is commodity volume divided by the displayed total. Confirm whether the denominator is all commodities or only the displayed top group. |
| <b>Latest Net Position by Commodity</b> | Latest long/short volume by commodity | Uses the latest selected Position date. Positive bars are long, negative bars are short; ranking is often by absolute magnitude.                   |
| <b>Trade Notional by Commodity</b>      | Contract-value concentration          | Ranks commodity notional. Use with volume and position to understand the driver.                                                                   |
| <b>Latest date label</b>                | As-of date for position charts        | The most recent Position date in the selected context, not necessarily today or calendar month-end.                                                |

**Do use the dashboard to**

- Monitor trading activity and concentration.
- Identify settlement and cash-flow movements.
- Compare Buy and Sell activity.
- Review open long and short volume positions.
- Find periods or commodities that require deeper investigation.

**Do not interpret it as**

- An audited accounting statement.
- A direct measure of revenue or profit.
- A complete market-risk or value-at-risk model.
- Proof that Pending items are overdue.
- A substitute for trade-level reconciliation and approval.

**Recommended governance**

Document metric owner, source table, refresh frequency, accepted status values, unit conventions and period comparator rules. Reconcile headline totals to source systems after any model or relationship change.

**Position filtering dependency**

A shared Commodity dimension should filter both FactTrading and Position. Without that relationship, a Commodity slicer can change trade visuals while leaving position visuals unchanged.

END OF DICTIONARY
